Diabetic retinopathy; Screening; Teleophthalmology

Abstract
Diabetic retinopathy (DR) is the leading cause of legal blindness in the United States. Considering the increasing incidence of DR, it is extremely important to detect the most cost-effective tools for DR screening, so as to manage this surge in demand and the socioeconomic burden it places on the health care system. Despite the advances in retinal imaging, analysis techniques are still superseded by expert ophthalmologist interpretation. Teleophthalmology presents an immense opportunity, with high rates of sensitivity and specificity, to manage the steadily increasing demand for eye care of patients with diabetes, but challenges remain in the delivery of practical, viable, and clinically proven solutions.

Rol de la tele-oftalmología en el cribado de la retinopatía diabética

RESUMEN
La retinopatía diabética (RD) es la causa principal de ceguera en los Estados Unidos. Teniendo en cuenta la creciente incidencia de RD, es extremadamente importante detectar las herramientas más económicas para su cribado, para poder gestionar esta demanda creciente, así como la carga socioeconómica que supone para el sistema sanitario. A pesar de los avances en términos de imagen retiniana, las técnicas de análisis siguen siendo reemplazadas por la interpretación de los oftalmólogos expertos. La tele-oftalmología se presenta...

Introduction

According to the American Telemedicine Association, Telemedicine is defined as the “the use of medical information exchanged from one site to another via electronic communications to improve a patient’s health status”. Due to the increasing needs for more accessible, financially affordable and effective healthcare services, telemedicine has emerged as an alternative method for the assessment of specialized evidence-based approach, which can be offered in a cost-effective manner especially in underserved and remote populations. Taking into account that the estimated number of diabetics projected to reach 642 million by the year 2040, the incidence of ocular complications secondary to diabetes is also expected to increase substantially. Historically, current screening strategies for detecting diabetic retinopathy (DR) have poor compliance, but technological development can enhance access to care. Establishing mechanisms to overcome geographic and financial barriers to access is vital for preventing visual disability. The burden of implying immediate and cost-effective screening for patients with diabetic retinopathy (DR) via distant imaging of the retina has become one of the most widely used applications of telemedicine in Ophthalmology.

The concept of teleophthalmology for the screening and management of patients with diabetic retinopathy

DR consists a leading cause of blindness all over the world, especially in the working-age population of developed countries. It must be underlined though that early detection and timely intervention can contribute in preventing the diabetes-related ocular complications. Lifelong routine retinal evaluation in combination with appropriate treatment have reduced the risk of severe loss of vision to less than 2% per person and 4% per eye. Typically, the retinal evaluation of eyes with DR is based on an in-person assessment with an eye care specialist and fundoscopy through dilated pupils. The purpose of the examination is to assess the severity of DR by detecting retinal lesions and provide clinicians adequate information in order to decide about the required therapeutic interventions and organize an appropriate follow-up. As can be inferred, due to the immense increase of the global number of patients with diabetes mellitus, the time investment needed from every ophthalmologist (in order to evaluate all diabetics at least once annually) will also rise exponentially over the next few years. Therefore, it appears that the concept of in-person examinations is neither practical nor sustainable in the settings of modern health care. Even if government and non-governmental agencies provide increased support, a large proportion of patients with DR will not receive the recommended minimum of an annual eye examination. A wide spectrum of psychological, social, medical and financial parameters (need for pupil dilation, patient’s age, educational status, health insurance coverage, transportation costs, poor patient awareness, and limited access to eye care services) can affect the effective implementation of recommended screening guidelines. Interestingly, even in urban areas with easier access to specialized eye care, the annual DR screening appointments can be missed due to the lack of awareness, the struggle in booking appointments and the long waiting times. The difficulty of adherence to the recommended annual retinal assessment of diabetics has been recorded in all socio-economic levels. The importance of routine retinal evaluations to identify eyes at risk for visual loss was recognized by eye care providers approximately 40 years ago. Nowadays, the diabetes-related visual loss affects significant rates of the population causing continuous strain at the health care systems. Although the traditional in-person strategy remains essential it may not be enough to meet the minimum standards for preventing visual loss. Therefore, the needs of modern health care call for an immediate modification in the overall approach of DR evaluation and for this reason the health systems have started using tele-ophthalmology to address this issue. Several studies from different countries have indicated that the implementation and use of telematic screening can be successful from patient, caregiver, and authorities’ point of view. Characteristically, Park and Mansberger reported the results of a multicenter randomized clinical trial that compared the effectiveness of telemedicine with non-mydriatic cameras to the traditional care by eye care providers. They underlined that telemedicine with non-mydriatic cameras detected diabetic retinopathy, as well as other visually significant eye disease, such as glaucoma or vascular occlusions.

Remote retinal imaging: accuracy and reliability

Tele-ophthalmology programs have facilitated the identification of DR cases by utilizing digital retinal imaging [Fig. 1]. Several studies have shown that the sensitivity (62.5%–98.2%) and specificity (76.6%–98.7%) of tele-ophthalmology in diagnosing DR are comparable to
those of the traditional clinical examinations.\textsuperscript{24,25} Boucher
et al.\textsuperscript{3} studied 291 cases of diabetic patients who underwent
DR screening using a non-mydriatic camera and clinical
examination (complete ophthalmological examination
and dilated fundoscopy) in a community-based population.
The fundus photographs were transmitted to the hospital
server through the File Transfer Protocol (FTP), in order
to be assessed; quality analysis was done at the hospi-
tal reading center. Of the 291 study participants, 81.7%
had fundus photographs of adequate quality for inter-
pretation. Additionally, the image quality was similar to their
previous studies.\textsuperscript{26,27} The use of non-mydriatic fundus imag-
ing facilitated screening thresholds for referrals of mild
non-proliferative DR (NPDR) and moderate NPDR with a sen-
sitivity of 97.1\% and 53.3\%, respectively, and specificity of
95.5\% and 96.9\%, respectively. Individuals with severe NPDR
were accurately detected 100\% of the time using a screening
threshold of mild retinopathy. Consequently, telemedicine
provided a reliable and highly acceptable tool for DR screen-
ing, as it can attract an important number of individuals
with diabetes and recruit patients that could be otherwise
missed by the current strategies of screening. A relevant
study by Perrier et al.\textsuperscript{29} compared two, three, and four
45-degree non-mydriatic fundus imaging with the ETDRS\textsuperscript{3}
standard stereoscopic 30-degree fields. In comparison with
the ETDRS standard fields, they found that using two 45-
degree non-mydriatic images sensitivity and specificity of
screening for mild or severe DR (ETDRS grade 35 or greater)
were 87.5\% and 92.3\%, respectively. On the other hand, using
3 and four non-mydriatic images provided corresponding val-
ues of 88.9\% and 94.6\%, and 88.9\% and 91.9\%, respectively.
Liesenfeld et al.\textsuperscript{30} compared the results of DR evaluation
of 129 cases by 2-field 50-degree non-stereoscopic digital
fundus images and by slit-lamp fundoscopy carried out by an oph-
thalmologist. The sensitivity of detecting eyes with DR at
risk [at least moderate NPDR and/or presence of clinically
significant macular edema (CSME)] using digital photography
among the reading centres varied from 70\% to 92\% (median,
85\%) and specificity varied from 73\% to 95\% (median, 90\%)
at a 95\% confidence interval (CI). It was recommended that
combining photography and measurement of visual acuity
could improve screening and threshold referral.
Gomez-Ulla et al.\textsuperscript{31} assessed the efficiency of digital reti-
nal images for the evaluation of DR. It was shown that there
was an agreement between DR grading from digital images
and clinical eye examination. Therefore it appears that the
digital fundus images correctly assessed the presence or
absence of DR.
Shi et al.\textsuperscript{32} carried out a systematic review and meta-
analysis of 20 articles and found that the pooled sensitivity
of telemedicine was higher than 80\% in detecting the
absence of DR and low or high risk PDR; higher than 70\%
in recording mild or moderate NPDR diabetic macular edema
(DME), and CSME; and 53\% in severe NPDR detection. Finally,
pooled specificity exceeded 90\%, with the exception of mild
NPDR, where specificity was 89\%.

Access and cost-effectiveness

The efficiency of a tele-ophthalmology program is based on
its ability to limit the burden on the health system by offer-
ing services to the target population by using limited health
care resources. Population-based interventions require two
important parameters; decent levels of diagnostic accu-
rac y and cost-effective evidence-based care.\textsuperscript{4} It has been
estimated that only 50\%-90\% of the population will need
specialized eye care, whereas less than 10\% will require fur-
ther management for vision-threatening DR.\textsuperscript{33} The in-person
clinical evaluation of diabetes-related retinal complications
may often be inefficient, taking into account that more
cost-efficient tools such as remote retinal photography are
gradually becoming more available.

Nathoo et al.\textsuperscript{34} reported the results of the assessment
of 394 diabetics (788 eyes) using tele-ophthalmology. Out
of them only 27.2\% had DR and over a 2-year interval
telemedicine contributed in saving approximately 450 round
trips, showing that tele-ophthalmology can be efficiently
used for DR screening. Although these figures indicate the
reduced travel time and cost for a rural-population it does not take into account the cost saved from time away from work or lost wages during eye consultations.

A relevant study for the rural population India studied the use of tele-ophthalmology as a tool for DR screening in order to assess its cost-effectiveness when compared with no screening. This study highlighted that the cost of quality-adjusted life-years (QALYs) for this application of telemedicine was cost-effective when compared to no screening at all. Despite the fact that DR monitoring via tele-ophthalmology programs was initially used for rural and distant populations with limited access to eye care, later studies indicated that it may also be useful in urban settings. Chin et al. utilized non-mydriatic fundus photography as a tool for DR screening among patients with poor compliance to their annual eye check-up in both rural (872 participants from remote medical clinics at Native American Indian reservations) and urban areas (517 patients from a primary care clinic at an urban academic medical center). All participants had a diagnosis for diabetes and confirmed that they have not had a dilated fundus examination within the last 12 months. Images acquired were sent electronically to a retinal specialist who carried out a remote review. It was shown that digital images were of sufficient quality for evaluation.

Tele-ophthalmology based on mobile imaging units can ameliorate DR screening and decrease the possibility of poor compliance or lost follow-up appointments. Digital images from both eyes of 3505 diabetics were acquired via 3 different mobile units around different provinces of Canada. After obtaining the fundus images, retinal specialists reviewed this material in order to organize further consultations and management of the disease. Interestingly, a mean of 85.6% individuals did not require a further referral, suggesting that ophthalmology assessments through telemedicine can save significant time and can contribute in prioritizing patients that need further interventions.

According to another study that was carried out in the United States higher rates of diabetics are keen on undergoing a tele-ophthalmology screening, while the vast majority of them does not require further follow-ups until their next annual examination. In a primary care setting, the long-term effectiveness of telemedicine in DR screening examinations in comparison with traditional clinical examination, may contribute more frequent screening examinations and can be considered as a useful tool for the monitoring of these patients. In a similar manner with the above mentioned studies, most patients did not warrant a further referral to an eye care specialist.

**Patients’ perceptions on tele-ophthalmology**

Telemedicine is a validated, cost-effective method to improve monitoring. However, the acceptability of telemedicine as a novel screening tool from patients consists one of the most important parameters of its efficiency. Patients appear to perceive tele-ophthalmology as a highly acceptable approach for their DR screening. After completing a relevant questionnaire the majority of patients (90.8%) expressed that they found it as a very acceptable method for monitoring if an ophthalmologist was not available. Furthermore, 82% (239 patients) declared their preference for

(b) Fundus photography of the right eye of a diabetic patient with severe diabetic macula edema, cotton wool spots and retinal hemorrhages. This is a case of a moderate to severe non-proliferative diabetic retinopathy that calls for treatment with panretinal laser photocoagulation and intravitreal injections with anti-VEGF (Vascular Endothelial Growth Factor) agents.

Table 1  Summary of major challenges in the implementation of tele-ophthalmology for diabetic retinopathy screening.

<table>
<thead>
<tr>
<th>Challenge</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Quality of care</td>
<td>Quality of care appears to be causing a significant degree of skepticism for ophthalmologists. This derives from the fact that tele-ophthalmology interferes with the classic attitude of a physician’s clinical examination and personal interaction with his or her patients.</td>
</tr>
<tr>
<td>Liability</td>
<td>Possible standard malpractice considerations have to be taken into account, especially in cases where there may be relevant gaps in the laws of each country.</td>
</tr>
<tr>
<td>Image quality</td>
<td>Teleophthalmology programs must take into account that the ungradable rate is a critical issue. In cases of an ungradable image, that encounter becomes unusable. The patient will not benefit, and it drains resources from the program. Reduction of ungradable images will increase the financial sustainability and clinical effectiveness of the program.</td>
</tr>
<tr>
<td>Workflow</td>
<td>Validated protocols are required in order to clearly delineate workflow and roles/responsibilities. Additionally, the time burden on physicians needs to assess all cases should also be estimated.</td>
</tr>
<tr>
<td>Security</td>
<td>Data encryption, password protection, and adherence to federal regulations, compliant backup and archiving must to be in accordance with all devices, from workstations to mobile devices.</td>
</tr>
<tr>
<td>Financing and reimbursement</td>
<td>Financial sustainability can be a substantial challenge, especially for programs that are not university-based or are not part of a federal program.</td>
</tr>
<tr>
<td>Patient perceptions</td>
<td>The patient’s attitude, satisfaction and compliance to a tele-ophthalmology program should be assessed at regular intervals.</td>
</tr>
<tr>
<td>Training of health care providers</td>
<td>All professionals involved in such screening programs must receive appropriate training regarding DICOM [Digital Imaging and Communications in Medicine] standards and compliance, regulations, as well as hardware and software that will be used.</td>
</tr>
<tr>
<td>Confusion of scope</td>
<td>Every tele-ophthalmology project should clearly define its scope, objectives and targets regarding the health care services provided.</td>

The role of tele-ophthalmology in diabetic retinopathy screening

In this type of screening over the traditional approach, as they considered it faster, easier, more accessible and convenient. Eighteen per cent of participants indicated that they would prefer a personal interaction, whereas 3.2% stated that they do not trust the validity of digital retinal imaging. Interestingly, 95% underlined their preference to have their next DR examination via a telemedicine system and be referred to an eye specialist only if required. Additionally, most of the participants (91%) signified their intention of being more compliant in the future if they are monitored with this new screening approach. Subsequently, tele-ophthalmology strategy for DR screening may persuade more individuals to attend a regular retinal screening. Similarly, a study conducted in Kenya revealed that diabetics find a tele-ophthalmology approach more convenient and helpful compared to traditional clinical examination.

Valikodath et al. explored the factors that may influence patients’ attitudes toward telemedicine. Their study showed that in overall patients were keen on participating in a telemedicine programme. Their attitudes were influenced by their perceptions and health, but not their demographics. Those individuals that were receptive focused on convenience, while those that were unreceptive underlined their patient-doctor relationship or having long-standing diabetes mellitus. The results from this study indicated that tele-ophthalmology should be designed for people who are in need and receptive to similar programmes.

The keys to successful implementation

The high costs of setting the initial capital outlay consist one of the primary burdens of a successful DR screening program. The two main investments are related with the staff training and the digital fundus cameras. Gomez-Ulla et al. analyzed the costs of tele-ophthalmology program in order to compare them with the clinical assessment by an eye specialist. The study took into account several factors including the capital expenditure, human resource component, lost time and wages of patients during screening, patient travel expenses, and the cost of subsequent consultation for patients who required further management. From the perspective of a public health system, the cost for clinical funduscopy is less due to the lower capital expenditure and maintenance costs. On the other hand, tele-ophthalmology offers lower travel costs and lost wages for the patients. Additionally, ungradable images because of poor field definitions, media opacities and small pupil size may cause further limitations to the implementation of telemedicine in DR monitoring. As can be expected due to the increased rates of cataracts in diabetic patients, telemedicine programs with digital non-mydriatic fundus cameras may have a higher percentage of ungradable images. The presence of images that cannot be properly graded lead to more referrals and in-person examinations with an ophthalmology and subsequently to increased expenses that diminish the cost-effectiveness of the program.

Overcoming the burden of ungradable retinal photographs and ensuring quality are both intricately correlated with the successful implementation and sustainability of such a program. Standardized and verified protocols, sufficient training of photographers, and probably allowing some re-adjustments through a defined protocol for selective mydriasis, if required, are some of the most substantial parameters. Some studies have underlined the importance of pupil dilation in improving the image quality in reducing the ungradability. It must be taken into consideration though that mydriasis may influence the patients’ perspective regarding telemedicine’s high acceptability.
probably, the implementation of scanning laser ophthal-
moscopy with ultrawide field (UWF) imaging technology
can contribute in obtaining images of higher quality with
a better field of view even in non-dilated patients. A
relevant study compared the rate of ungradable retinal
photographs between non-mydriatic multifield fundus pho-
tography (NMFP) and non-mydriatic UWF imaging. The study
showed that the ungradable rate per patient was substan-
tially lower in images acquired from UWF imaging compared
to NMFP. Notably, non-mydriatic UWF imaging limited the
amount of images that could not be graded by 81%. More-
over, UWF imaging increased the ability of detecting DR from
11.7% to 24.2% (P < 0.0001) and referable DR (moderate
NPDR or DME or worse) from 6.2% to 13.6% (P < 0.0001).
Finally, more severe cases of DR could be detected based
on the existence of mainly peripheral lesions observed only
with UWF images, suggesting that UWF can be very helpful
in organizing large population-based tele-ophthalmology DR
screening programs.

In conclusion, the results of such a program are not
immediate, and may be moderate in the early years
of the implementation, before they gradually start to
improve. Although early recognition and treatment of
diabetic retinopathy is of proven value in reversing or pre-
venting loss of vision, the infrastructure to detect cases
that require treatment is not yet universally available.2
The familiarity of patients and primary care providers with
tele-ophthalmology needs to be enhanced, so that issues
regarding compliance will be curtailed. Consequently, in
order to ensure good medical practice and provide quality
health care services, tele-ophthalmology programs need to
be well organized and ready to encounter their main chal-
lenges [Table 1].

Conclusions and future perspectives

The national DR screening tele-ophthalmology program in
the United Kingdom has been described as one of the most
successful programs. It has underlined the importance of
monitoring DR and its complications together with alter-
ations of the overall glycemic status. Notably, DR is not any
longer considered as a leading cause of blindness in England
and Wales.3 The concept of this program was to identify the
target population and provide a functional referral system
for patients that required further management. Addition-
ally, a continuous program of quality assurance and control
was carried out.

A multidisciplinary collaborative approach for DR screen-
ing must be undertaken by more countries in order to
improve retinopathy evaluation rates. A primary care physi-
cian or an endocrinologist can be the first point of contact
for the majority of the diabetics, as this strategy can
increase the probability of having a retinal screening.4
Therefore, if primary care or multispecialty clinics are
equipped with fundus cameras, especially in areas without
access to eye care specialists. Interestingly, several studies
have shown that properly trained primary care physicians
can reliably evaluate fundus images.5,6 Decent training and
education on diabetes and its ocular complications can fur-
ther improve our understanding and improve the screening
among diabetics.7 Future studies and randomized control

trials are required in order to improve our strategies and
approach leading to improved tele-ophthalmology services
that will cover efficiently a wider population.
