Conjunctiva

ABSTRACT

Purpose: To characterize diurnal variations in scleral morphological parameters and assess correlations between lifestyle habits and variations in these parameters.

Methods: This prospective observational study enrolled healthy adult participants. Corneo-scleral morphology was evaluated at five standardized timepoints (9:00, 11:30, 14:00, 16:30, and 19:00) using the Pentacam HR corneo-scleral profile module. Participants completed a lifestyle questionnaire assessing sleep patterns and daily routines. Primary outcome measures included sagittal height (SH) and bulbar slope (BS), with coefficients of variation (CV) across the day calculated for each parameter.

Results: A total of 109 eyes from 55 participants (mean age: 32.6 ± 12.6 years; 37 female, 18 male) were analyzed. Repeated-measures analysis revealed no statistically significant diurnal variations in scleral parameters (all p-values ≥ 0.069). Secondary analysis identified some significant correlations between CVs of scleral parameters and specific lifestyle habits: washing face in the morning (minimum BS, $p = 0.007$), having breakfast (minimum SH, $p \leq 0.016$), drinking coffee in the morning (SH $p \leq 0.040$), drinking coffee during the day (mean SH $p = 0.016$), and screen exposure before bedtime (mean SH $p = 0.036$). Statistically significant sex-related differences were observed in minimum BS of the right eye ($p = 0.020$) and astigmatic SH ($p = 0.042$).

Conclusions: The corneo-scleral profile of healthy eyes remains stable throughout the day, with no significant diurnal changes in SH or BS. Although certain lifestyle habits showed trends toward association with scleral variation, definitive conclusions cannot be drawn.

Introduction

The geometry of the anterior sclera and conjunctiva plays a key role in contact lens fitting, ocular biomechanics, and the design of anterior segment procedures. Accurate understanding of this morphology is critical for tailoring medical devices and improving patient outcomes.

Sclero-conjunctival morphology is influenced by both intrinsic and extrinsic factors.^{1–11} Intrinsic factors include age-related changes and ocular conditions like myopia or keratoconus. Age influences corneo-scleral shape,^{1,2} with older individuals and males exhibiting greater scleral thickness.³ Myopia also alters scleral structure, increasing sagittal height (SH)⁴ and reducing biomechanical scleral stiffness.⁵ Accommodation and convergence flatten the nasal scleral surface, particularly in myopic eyes.^{6,7} Similarly, irregular corneas exhibit distinct scleral shapes compared to regular corneas.^{8,9} Keratoconus specifically alters the sclera adjacent to the limbus.^{10,11} It should be noted that the conjunctiva is a

transparent mucous membrane that conforms to the underlying scleral topography, adapting dynamically to its geometric variations.¹²

Extrinsic factors influencing sclero-conjunctival morphology include contact lens wear. Spherical soft contact lenses induce more significant corneo-scleral deformation than toric designs.¹³ Extended soft lens wear increases limbal curvature,¹⁴ while mini-scleral lenses flatten the corneo-scleral profile, enlarging the limbal radius.¹⁵ Notably, mini-scleral lenses also reduce scleral thickness.¹⁶

Despite significant advances in characterizing anatomical and lens-induced changes in the sclera, little is known about potential circadian or diurnal fluctuations. This represents a relevant gap, as time-dependent variations could impact the accuracy of measurements and the repeatability of device fitting. Elucidating these diurnal, time-dependent changes could optimize measurement protocols for clinical applications, including improved fitting strategies for certain contact lens designs. This study aimed to quantify daily fluctuations in scleral morphological

Table 1

Questionnaire on daily habits and activities.

	Question	Outcome
Morning Assessment		
1	What time did you go to sleep and wake up?	Bedtime, wake-up time, total sleep duration (hours)
2	Do you suffer from sleep apnea?	Yes/No
3	Did you have breakfast this morning?	Yes/No
4	Do you drink water upon waking up?	Yes/No
5	Did you have coffee this morning?	Yes/No
6	Did you wash your face this morning?	Yes/No
7	Did you apply eye drops/artificial tears this morning?	Yes/No
8	Did you rub your eyes this morning?	Yes/No
9	Did you exercise during the morning? If so, what was the intensity and duration?	Yes/No, intensity (light/moderate/intense), duration (hours)
10	Were you exposed to screens last night before falling asleep?	Yes/No
Evening Assessment		
11	Did you drink coffee during the day? If so, how many cups?	Yes/No, number of cups
12	Are you a smoker? If so, how many cigarettes did you smoke during the day?	Yes/No, number of cigarettes smoked
13	Did you exercise during the day? If so, what was the intensity and duration?	Yes/No, intensity (light/moderate/intense), duration (hours)
14	Did you consume alcohol during the day?	Yes/No
15	Did you experience a stressful event during the day?	Yes/No
16	How many hours did you spend using screens today?	Total screen time (hours)
17	Did you take a nap during the day? If so, for how long?	Yes/No, total nap time (hours)
18	How many hours did you read without using digital screens?	Total non-digital reading time (hours)

parameters, and to investigate their potential associations with self-reported lifestyle habits such as sleep, diet, and screen exposure.

Methodology

Participants

This prospective study was conducted at the Optometry Clinic of the University of Alicante (Spain). The protocol adhered to the Declaration of Helsinki and received approval from the University of Alicante Ethics Committee (UA-2023–01–19_2). All participants provided written informed consent prior to enrollment. Eligible participants met the following criteria: absence of ocular pathology (confirmed by comprehensive slit-lamp examination), no history of ocular surgery, corrected distance visual acuity (CDVA) of 20/25 or better, and intraocular pressure within the normal range (10–21 mmHg). Contact lens wearers underwent mandatory washout periods: a minimum of 14 days for soft contact lenses, and a minimum of 28 days for rigid gas permeable (RGP) contact lenses. These intervals exceed the established corneal recovery timelines (1–2 weeks for soft lenses, 3–4 weeks for RGP lenses) to ensure full stabilization of corneoscleral morphology.

Measurement protocol

All measurements were performed by a single experienced examiner (L.B.B.) using standardized protocols to ensure consistency. The initial evaluation was performed at 09:00 (± 30 min) and included measurement of CDVA, manifest refraction, and ocular biometry (mean of 3 consecutive measurements) assessed using the IOLMaster 500 (Carl Zeiss Meditec, Germany). A slit-lamp biomicroscopic examination was performed to detect ocular abnormalities.

Corneoscleral topography was evaluated using the Pentacam HR system (OCULUS Optikgeräte GmbH, Wetzlar, Germany) equipped with the corneoscleral profile (CSP) module. For this study, parameters were collected over a 15 mm analysis zone. Although the Pentacam CSP can capture up to 18 mm,¹⁷ measurements in the superior region are often limited by the eyelid, making full coverage difficult. Therefore, the 15 mm zone was chosen to ensure reliable data capture in all participants. Parameters included: maximum, minimum, mean, and astigmatic SH (defined as maximum minus minimum SH); corneal and scleral best-fit spheres (BFS); and maximum and minimum bulbar slope (BS). The BS is a built-in parameter computed by the Pentacam HR CSP software,

which quantifies the inclination of the scleral surface relative to the corneal tangent, and is expressed as an angle. These measurements were repeated at four additional timepoints —11:30, 14:00, 16:30, and 19:00—with a tolerance of ± 30 minutes for each session.

In addition, participants completed an ad-hoc lifestyle habits questionnaire (Table 1) designed to assess sleep patterns, caffeine and alcohol consumption, physical activity, screen exposure, and other daily behaviors. The questionnaire was divided into morning and evening sections: the morning portion addressed behaviors upon waking, while the evening portion focused on daytime and pre-sleep habits.

Sample size

The sample size of eyes in this study was determined to ensure that the objectives could be consistently achieved, while also being large enough for statistically significant effects to be clinically meaningful. A review of the existing literature showed that, to date, no studies have comparatively analyzed diurnal changes in corneo-scleral morphology in healthy subjects. Therefore, a study evaluating changes in central corneal thickness in healthy subjects was used as the closest available reference.¹⁸

The sample size was calculated using the online GRANMO sample size calculator. Assuming that the standard deviation of the amplitude of change was 0.008 mm, a minimum detectable difference of 0.0034 mm, an expected average dropout rate of 20%, a statistical power of 80%, and an α error of 0.05, the required number of eyes in the healthy population group was calculated to be 55.

Statistical analysis

Statistical analysis was conducted using SPSS software (version 29.0.1; IBM Corp., Chicago, IL, USA), with p-values < 0.05 considered statistically significant. Data normality was assessed using the Kolmogorov-Smirnov test (or the Shapiro-Wilk test for sample sizes < 50). For longitudinal comparisons across the five time points, both repeated-measures analysis of variance (ANOVA) (for parametric data) and the Friedman test (for non-parametric data) were applied. Pairwise post hoc comparisons were performed using the Bonferroni test for normally distributed variables and the Bonferroni-adjusted Wilcoxon test for non-normally distributed data variables.

The coefficient of variation (CV) was calculated as (within-subject standard deviation/mean)×100%. Differences in CV between groups based on habit-related responses were analyzed using the Mann-Whitney U test. Correlations between CVs and baseline clinical variables were assessed using Pearson's correlation coefficient for parametric data and Spearman's rank correlation coefficient for non-parametric data.

The change from baseline at each timepoint i (δ_i) was calculated as $100\% \times (\text{value at timepoint}_i - \text{parameter at baseline}) / \text{parameter at baseline}$.

Results

A total of 109 eyes from 55 subjects (aged 18–67 years; mean $\pm$ SD: 32.6 ± 12.6 years) were evaluated. Measurements were taken at $09:06 \pm 19$ min, $11:27 \pm 17$ min, $13:58 \pm 23$ min, $16:27 \pm 19$ min, and $18:49 \pm 14$ min. The sample comprised 37 women and 18 men, including 55 right eyes (RE) and 54 left eyes (LE). Mean spherical equivalent was -1.32 ± 2.31 D (RE) and -1.19 ± 2.23 D (LE). Mean axial length (AL) was 23.90 ± 1.13 mm (RE) and 23.89 ± 1.13 mm (LE). Participants reported an average sleep duration of 7.14 ± 1.04 h the night before measurements, with a mean time of 2.08 ± 0.84 h between waking and the first measurement. Descriptive statistics for self-reported lifestyle habits are summarized in Table 2.

Changes throughout the day

Mean values of each scleral parameter at all timepoints are summarized in Table 3, along with the corresponding CVs and p-values from inter-timepoint comparisons. No statistically significant differences

Table 2

Distribution of daily habits in the study population.

Variable	Yes		No	
	n	%	n	%
Sleep apnea diagnosis	2	3.6	53	96.4
Had breakfast	36	65.5	19	34.5
Drank water in the morning	29	52.7	26	47.3
Drank coffee in the morning	31	56.4	24	43.6
Washed face in the morning	49	89.1	6	10.9
Applied eye drops	4	7.3	51	92.7
Rubbed eyes	26	47.3	29	52.7
Exercised in the morning	8	14.5	47	85.5
Used screens before bedtime	46	83.9	9	16.4
Drank coffee during the day	35	63.6	20	36.4
Smoked (current smokers)	9	16.4	46	83.6
Exercised during the day	13	23.6	42	76.4
Consumed alcohol	1	1.8	54	98.2
Experienced a stressful event (that day)	14	25.5	41	74.5
Took a nap	3	5.5	52	94.5
Read (non-digital content)	27	49.1	28	50.9

were observed in scleral parameters across the day. Figs. 1 and 2 display violin plots illustrating the change from baseline at each timepoint (δ) for each scleral parameter.

Correlations with lifestyle habits and descriptive variables

Statistically significant differences in the CVs of scleral parameters were observed for only a few lifestyle-related habits (Table 4). No significant correlations were found between scleral parameters and axial length (all $p \geq 0.263$) or total screen time (all $p \geq 0.332$). Additionally, no significant differences in scleral parameter CVs were found between individuals who did or did not engage in the following habits: morning water intake ($p \geq 0.333$), smoking ($p \geq 0.076$), morning physical activity ($p \geq 0.258$), daytime physical activity ($p \geq 0.112$), eye rubbing ($p \geq 0.090$), and reading from non-digital media ($p \geq 0.096$).

However, some significant correlations were identified in scleral parameter CVs and specific lifestyle behaviors. These included: washing the face in the morning (minimum BS RE; $p = 0.007$), having breakfast (minimum SH RE and LE; $p = 0.016$ and $p = 0.001$, resp.), drinking coffee in the morning (mean SH RE and maximum SH; $p = 0.011$ and $p = 0.040$, resp.), drinking coffee during the day (mean SH RE and scleral BFS RE; $p = 0.016$ and $p = 0.040$, resp.), screen exposure before bedtime (mean SH RE $p = 0.036$), and experiencing a stressful event (maximum BS RE and mean SH RE; $p = 0.031$ and $p = 0.034$, resp.). In addition, statistically significant sex-related differences were observed in the RE for minimum BS ($p = 0.020$) and astigmatic SH ($p = 0.042$). Figs. 3 and 4 illustrate these associations.

Table 4

Statistically significant correlations between scleral parameters, lifestyle habits, and demographic variables.

Variable	Parameter	Eye	p-value	Correlation Coefficient (r)	Contralateral Eye (p;r)

Discussion

This is the first reported study to analyze changes in scleral geometry throughout the day. Although some fluctuations were observed in scleral parameters, no statistically significant changes were detected in BS or SH across timepoints. The magnitude of variability observed was consistent with the intrasession repeatability limits of the imaging system.

Bandlitz et al.¹⁹ reported that the CSP module demonstrates good repeatability for mean SH, with a mean difference of $-0.9 \mu\text{m}$. In our study, variability for this parameter was slightly higher, showing mean CVs of $0.70 \pm 0.39\%$ and $0.88 \pm 0.69\%$ for the right and left eye, respectively. Yang et al.²⁰ found CVs below 0.96% for mean SH, below 3.65% for mean BS, and below 29.95% for astigmatic SH in healthy eyes. Our results support these findings, suggesting that the observed variability falls within the instrument's repeatability limits.

In contrast, a study by Read et al. reported significant diurnal changes in scleral thickness, particularly in the temporal quadrant.²¹ They observed peak thickness upon awakening and minimum values around midday. Although our measurements did not reveal statistically significant diurnal changes in scleral morphology, a non-significant decrease in BS at 11:30 was noted. This trend is consistent with Read et al.'s²¹ observation of a corresponding decrease in corneal thickness at that time, suggesting a possible shared physiological mechanism. The apparent stability of scleral geometry throughout the day supports its reliability as a baseline for contact lens fitting. Our findings confirm that SH remains stable in the short term, with no significant diurnal changes that could impact scleral lens fitting. Consequently, any variation in lens fit or position during wear is more likely due to lens-induced effects, such as mechanical indentation or deformation, rather than inherent changes in scleral morphology. Macedo-de-Araujo et al.⁸ demonstrated that scleral lens wear can induce changes in SH and reduce tangent

angles in the nasal region at 7.5 mm and 8.00 mm chord lengths. However, our results indicate that diurnal rhythms do not meaningfully influence these parameters in the absence of lens wear and, therefore, scleral lens fitting.

Some lifestyle factors showed weak but statistically significant correlations with variations in scleral parameters. These correlations were asymmetrical between eyes, raising the possibility that habitual sleeping position may influence in scleral dynamics. Previous studies have linked sleeping posture to keratoconus progression, intraocular pressure fluctuations, and upper eyelid laxity.^{22–24} Notably, many of the most pronounced ocular changes—such as shifts in central corneal thickness and intraocular pressure—occur shortly after awakening. It is worth noting that the first measurement in this study was obtained approximately two hours after awakening, which may have missed some early-morning fluctuations. Such short-term changes could partly contribute to the diurnal stability observed in scleral morphology. This pattern suggests that mechanical pressure from the eyelids during sleep could contribute to morning asymmetries in ocular shape. Thus, sleeping position may partially explain the observed interocular differences in scleral CVs reported in this study. Despite limited correlation strengths ($r \leq 0.378$), certain statistically significant trends emerged: participants with shorter sleep duration exhibited greater variation in BS and SH, and those with longer intervals between awakening and the first measurement displayed increased diurnal variability in minimum, mean, and astigmatic SH. Additionally, sex-based differences were noted, with women showing greater variation in minimum BS and astigmatic SH compared to men. However, these findings should be interpreted with caution due to the sample size and variability across groups.

This study has several limitations. First, no measurements were collected immediately upon awakening or during nighttime, which may have excluded time points critical for characterizing full diurnal patterns. Second, although interocular asymmetries were observed, the potential role of sleep posture (e.g., ipsilateral vs. contralateral eye contact with the pillow) was not evaluated. Therefore, the influence of sleep position on interocular asymmetries remains untested, highlighting the need for future studies to consider this factor. Third, the study sample was limited to healthy eyes; future investigations should include individuals with ocular surface disorders or ectatic diseases to determine if similar stability is preserved. Finally, our analysis focused on parameters measured within a 15 mm diameter, which may have missed regional or quadrant-specific changes in scleral geometry.

This study provides the first evidence of diurnal stability in the corneoscleral profile of healthy eyes, with no clinically meaningful changes observed in SH or BS. Observed fluctuations remained within the established repeatability limits of the CSP module, confirming the temporal reliability of these measurements. While statistically significant associations with lifestyle habits were limited, preliminary trends suggested possible relationships between scleral variability and factors such as sleep duration, breakfast consumption, and timing of the first measurement. These findings underscore the need for further research into how behavioral and physiological rhythms may influence ocular surface geometry.
